

What is computing?

- Computer used to be a profession, a career
- Ada Lovelace proposed the Analytical Engine
- Alan Turing solved all algorithms with a system of data manipulation.
- Binary system... Easily represented by electronic signals
- Von Neumann makes EDVAC, Computer with memory
- Richard Feynmann → Quantum computing

Computación actual

Lenguajes de programación

- Declarative: Relationships between variables

- Imperative: It's about a route to a goal... algorithms

Finite list of instructions

- C is like latin

- Python tries to be more easy to read/write

Python !

Understandable
by computers

Low level

vs.

High level

Broadly applicable,
lacks specialized features

General

vs.

Specialized

Executes line by line

Interpreted

vs.

Compiled

Understandable
by humans

Are converted to machine code
and then executed. Usually more
efficient and gives more control

Syntax $\langle \text{variables} \rangle$ or $\langle \text{objects} \rangle$: \perp , 'abc', true, 1.0
 int string boolean float

$\langle \text{operators} \rangle$: + - * ** / // % Arithmetic
 plus minus times power division floor division modulus

== != <> < > <= >= Comparison
 equal not equal less than greater than less than or equal to greater than or equal to

set value →
 reset value →

 $x \langle \text{arithmetic operator} \rangle = y$
 is equivalent to
 $x = x \langle \text{arithmetic operator} \rangle y$

$x += y$
 Ex. is equivalent to
 $x = x + y$

Logical
 and or not

Bitwise
 & | ^ ~ << >>

$\langle \text{object} \rangle \langle \text{operator} \rangle \langle \text{object} \rangle = \langle \text{expression} \rangle$

Print statement: print($\langle \text{expression} \rangle$) Ex. 5 / "platzi" ... semantic error

Object Values in memory that can be referenced

method `type()` → `type("name") = string`

Clean code Name variables with relevant words

Reserved words

False	await	else	import	pass
None	break	except	in	raise
True	class	finally	is	return
and	continue	for	lambda	try
as	def	from	nonlocal	while
assert	del	global	not	with
async	elif	if	or	yield

Strings

- Character chain
- Between ' ' or " "

Usual operations

- Concatenate:
 - `"str_1" + "str_2" = "str_1str_2"`
 - `f'Hello world {"!" * 3}' = "Hello world !!!"`
- Length: `len('Hello') = 5`
- Indexing: `my_str = "Hello" → my_str[2] = "l"`
- Slicing:
 - `my_str[:2] = "He"`
 - `my_str[2:] = "llo"`
 - `my_str[::-2] = "Hlo"`

Floors An approximation...

Because numbers must be converted to binary code, there can be weird situations with floats. Ex.

$$0.1 \times 10 = 0.99999\dots$$

It is better to use `>` or `<` instead of `==` with floats

Inputs nombre = input("Cuál es tu nombre?")

Conditionals and or not Truth table

if <condition>: <expression>	A	B	A and B	A or B
elif <condition2>: <expression2>	T	F	F	T
else: <expression3>	T	T	T	T
	F	T	F	T
	F	F	F	F

Loops

while for iter

break to get out of the loop prematurely

Enumerate

Every possibility... brute force

Binary search

Must have ordered assets to work with.

- Cuts the array in half and uses the half where the object it is looking for is located. Over and over again until found.

If you are looking for number 8 in a 9-number array: STEPS.

ABSTRACTION - Use of libraries

Decomposition - Divide the code in functions

Functions

def <name>(<parameters>):
 <body>
 return <expression>

↳ - Can have a default value (not mandatory to use)
 - Can be declared on call
 ↳ keyword

Scope and frames

Scope Python

Es el contexto al que pertenece una variable en el programa de Python

¿En qué partes del programa puedo usar una variable?

Scope global

Si creas una variable en el cuerpo principal del código de Python, puedes usarla en cualquier parte

```
x = 'Esta es una variable global'  
def funcion():  
    print(x)
```

funcion()

print(x)

Puedes crear una variable local con el mismo nombre de una variable global, pero Python lo leerá como 2 variables distintas

```
x = 'Esta es una variable global'  
def funcion():  
    x = 'Y esta es una variable local'  
    print(x)
```

funcion()

print(x)

Scope local

Si creas una variable dentro de una función, esta pertenece sólo a esa función

```
def funcion():  
    x = 'esta es una variable local'  
    print(x)
```

funcion()

También puedes usar la variable en una función dentro de otra función

```
def funcion():  
    x = 'esta es una variable local'  
    def funcion_interior():  
        print(x)  
    funcion_interior()
```

funcion()

Keyword global

Puedes crear una variable global dentro de una función usando el keyword `global`

```
def funcion():  
    global x  
    x = 'Esta es un variable global'
```

funcion()

print(x)

También puedes cambiar el valor de una variable global con este keyword

```
x = 'Esta es una variable global'  
def funcion():  
    global x  
    x = 'Y ahora cambiamos su valor'
```

funcion()

print(x)

```

def func1(un_arg, una_func):
    def func2(otro_arg):
        return otro_arg * 2

    valor = func2(un_arg)
    return una_func(valor)

un_arg = 1

def cualquier_func(cualquier_arg):
    return cualquier_arg + 5

func1(un_arg, cualquier_func)

```

Contexts

Global

func1
un_arg
una_func
cualquier_func

func1

un_arg
una_func
func2
valor

func2

otro_arg

cualquier_func

cualquier_arg
un_arg

Docstrings

- Documentation with:
- What the function does
- Parameters used by the function
- What the function returns

"q" To quit docstrings in terminal

Recursion

- "Divide and conquer"
- Call to itself

Ex. Factorial

$$n! = \prod_{i=1}^n i \rightarrow \text{Normal loop}$$

$$n! = n \cdot \underbrace{(n-1)!}_{\downarrow} \rightarrow \text{Recursive}$$

Factorial definition inside Factorial definition

$$\text{Ex. } 3! = 3 \cdot 2! \rightarrow 3! = 3 \cdot 2 \cdot 1$$

$$2! = 2 \cdot 1!$$

$$1! = 1$$

Python recursion limit

Danelia Sanchez Sanchez Estudiante · el año pasado

Desconocía totalmente que Python tuviera un límite de recursividad. Para conocerlo hay que importar la librería sys:

```
>>> import sys
>>> print(sys.getrecursionlimit())
1000
```

Para modificar ese límite

```
sys.setrecursionlimit(n) # n es el nuevo límite a establecer
```

<https://www.geeksforgeeks.org/python-sys-setrecursionlimit-method/>

Funciones como objetos

- Las funciones:
- Tienen tipo
 - Se pueden pasar como argumentos de otras funciones
 - Se pueden utilizar en expresiones $<\text{Función}> == \text{"holá"}$
 - Se pueden incluir en varias estructuras de datos

Tuples

- Immutable sequence of objects \rightarrow Can be reassigned
- Can be used with return statement `return (1, 2)`
- Defined with parenthesis unlike lists
 - `my_tuple = (1, 2)`
 - `my_list = [1, 2]`
- Can use an specific value ... `my_tuple[0]`
- Define one element tuple with a comma... `my_tuple = (1,)`
- Unpack to variables... `x, y, z = my_tuple`,
 \hookrightarrow Must have same amount of elements as variables

Ranges

- integer sequence with start, finish and pace.

- Unmutable \uparrow Finish - NOT INCLUDED

`range(0, 10, 2)`
 \downarrow Start \downarrow Pace

`id()` method to get object's id

`range(0, 7, 2) == range(0, 8, 2)` \rightarrow Value equality

`id(range1) is id(range2)` \rightarrow Object equality

\downarrow
False!

`for i in range(0, 101, 2):
 print(i)` \rightarrow List every odd number from 0 to 100

Lists

- Mutable
- Modify lists may cause side effects
- Iterable

Functions: Modify \rightarrow `my_list[0] = 5` \rightarrow Assign value to a place

- Append
- Pop
- Remove
- Insert
- Remove
- Extend
- Copy
- Clear
- Index
- Count
- Sort
- Reverse

Clone a list `list(a)` or `b = a[:]`

List comprehension - Use operations along a list
 - Conditions to filter

Documentation <https://docs.python.org/3/tutorial/datastructures.html>

Dictionaries - Lists with keys instead of index
 - No order
 - Hashmaps - Hashing function
 - Mutable
 - Iterable

`my_dict = {`

Tests

- Black box tests**
- It's based on method description, not implementation
 - Try inputs validating outputs
 - Unit testing or integration testing

class, test driven development

- Crystal box tests**
- Program flow
 - Test possible paths
 - Regression testing or mocks

if - Test if, elif, else

Recurions & loop - No loop

- Just once
- A lot of times

while - Break conditions

- False entry conditions

Debugging

- Print statement > debugger
- Scientific method
- Open mind
- Keep in mind what you've tested

search... Binary search with print statements

Exceptions

- Code errors, common errors
- Defensive programming
- Key words:
 1. Try
 2. Except
 3. Finally
- Don't silence exceptions
- Send exceptions with "raise"

EAFP Easier ask for forgiveness than permission

try:

```
    return países [pais]           vs.      Verifying the existence of
except KeyError:                  "pais" before
    return None
```

Affirmations

- verify object types

```
assert <boolean>, <error message>
```
